version	1.0.1
scope	Example. This code is provided as example code for a user to base their code on.
description	How to write to a file during execution
boards	Unless otherwise specified, this example runs on the SliceKIT Core Board, but can easily be run on any XMOS device by using a different XN file.
The UTIME company to be seen boundly support calls on boboli of the toward ownline.	

The xTIMEcomposer tools can handle system calls on behalf of the target application. This handling is enabled by default.

A file can be opened for writing as follows:

An open file can be written using the _write system call

```
if (_write(fd, "hello there!", 13) != 13) {
    printstrln("Error: _write failed");
    exit(1);
}
```

We can then close an open file using the _close system call

```
if (_close(fd) != 0) {
    printstrln("Error: _close failed.");
    exit(1);
}
return 0;
}
```

Compile the above code. When the resulting executable is run, a file called test.txt containing 'hello world!' is written to the current working directory.

Note: In this case we are using the raw system call functions directory as we are working in XC. However, if working in C then it might be advisable to the the C std library equivalents: *fopen*, *fwrite* and *fclose*.
